Abstract

Based on an argument for the noncommutativity of momenta in noncommutative directions, we arrive at a generalization of the $\mathcal{N} = 1$ super E^2 algebra associated to the deformation of translations in a noncommutative Euclidean plane. The algebra is obtained using appropriate representations of its generators on the space of superfields in a $D = 2, \mathcal{N} = 1$ “noncommutative superspace.” We find that the (anti)commutators between several (super)translation generators are no longer vanishing, but involve a new set of generators which together with the (super)translation and rotation generators form a consistent closed algebra. We then analyze the spectrum of this algebra in order to obtain its fundamental and adjoint representations.

1 Introduction

Supersymmetry (SUSY) has been the basic ingredient in most of the recent attempts towards formulating a unified fundamental theory of the nature. Besides its merit for solving some important theoretical shortcomings of the standard particle physics, it has also played a central role in recent developments of string theory [1]. For being a consistent fundamental description of nature, string theory depends on SUSY at least at the level of the string worldsheet. This in turn leads to a few number of consistent spacetime SUSY theories including all the well known types of superstring theories. All these string theories at their low energy level reduce to SUSY effective field theories from which the supergravity and super Yang-Mills (SYM) theories are the most famous examples [2].

One of the important consequences of string theory is the emergence of the spacetime noncommutativity at short distances (for a recent review see [7]). It is shown that this noncommutativity of spacetime is equivalent to deforming the algebra of functions on the spacetime manifold by replacing their ordinary products with the so called Moyal products. This type of noncommutativity was initially appeared in the context of Matrix theory compactifications on a torus [3, 4]. The more recent occasion of noncommutativity in string theory was that for the open strings ending on a D-brane within a background B-field [5]. In both cases, the low energy limit turns out to be a noncommutative gauge theory which is expected to be supersymmetric because of the SUSY underlying the fundamental theory. Thus we are led to NCSYM theory as the worldvolume theory of a D-brane.

It is well known that BPS D-branes of string theory are SUSY extended objects preserving 1/2 of the total spacetime SUSY and they possess the same amount of supercharges on their worldvolume theories [2]. One may suspect that whether the amount of SUSY on a brane is changed by the presence of a B-field, and further, if a B-field modifies the algebra of the supercharges on the brane. A direct computation of the worldsheet (super)charges reveals that the answer to both questions is negative; i.e. the presence a (constant parallel) B-field does not alter the SUSY properties of a D-brane [8]. This leaves open, however, the possibility of a deformation of the SUSY algebra in a more general given background. In fact, in [9] it is shown that a constant H-field ($H = dB$) deforms the spacetime superalgebra, using explicit expressions for the conserved worldsheet (super)charges.

Whether the prediction of string theory is about SUSY in the presence of background fields, it is worthwhile in its own respect to know how

the spacetime noncommutativity may influence the superalgebra underlying a SUSY field theory. The first attempts in this direction were made in refs.[8, 10, 16] (see also [11]-[13] for more recent works). The deformation proposed in [10] was based on the deformation of the algebra of superfields on a so-called “noncommutative superspace”. This is defined by the algebra of the bosonic and fermionic operators (x^μ, θ^α) (corresponding to the grassmann even and odd) coordinates of the ordinary superspace obeying non-trivial (anti)commutation relations among themselves. This leads to a new generalized version of the Moyal product between superfields involving a deformation of the products of functions of the odd coordinates similar to that of the even coordinates (for a general deformed version of the grassmann algebrasee [14], and [15] for a non-anticommutative field theory). It was found, however, that (at least for the $D = 4, \mathcal{N} = 1$ case) the only deformation compatible with supertranslation and closure of the chiral superfields under the generalized Moyal product is the one in which θ ’s anti-commute with themselves and commute with x ’s, as usual, but x ’s can still be noncommuting.

On the basis of the above result the authors of [10, 16] have constructed deformed versions of the usual Wess-Zumino model and SYM theory with $\mathcal{N} = 1$ SUSY in four dimensions. Deformations of the $\mathcal{N} = 2, 4$ SYM theories have been studied in refs. [22, 23, 24] and that of SUSY Born-Infeld action in [10, 25, 26], and the deformed version of the non-linear sigma-models was considered in [27, 28]. In all these cases, the deformed theory is obtained from its commutative counterpart simply by replacing the ordinary products of fields with the Moyal products. The renormalizability and 1-loop effective actions of SUSY NCFT was studied in refs. [17]-[24]. Typically, noncommutativity turns a renormalizable theory to a non-renormalizable theory due to the UV/IR mixing phenomenon [29]. However, the addition of SUSY restores the renormalizability of the theory and moreover results in the non-renormalization of its parameters [17]-[24].

More recently, some authors have considered the issue of noncommutativity in quantum mechanics (QM) [31]-[38]. The main problem of the NC-QM is to find the spectrum of states for a particle in a specific potential assuming that its coordinates (q^i) do not commute. The momenta of the particle (p_i) may be commuting or non-commuting depending on the given problem. Generically, the commutation relations of (q^i, p_i) have the following form:

$$[q^i, q^j] = i\Theta^{ij}, \quad [q^i, p_j] = i\delta_j^i, \quad [p_i, p_j] = i\Phi_{ij}. \quad (1)$$

This situation is somehow familiar from the ordinary QM of charged particles on a plane in a constant (transverse) magnetic field and is well known as the Landau problem [31]. Of course, for the ordinary (commutative) Landau problem we have $\Theta^{ij} = 0$, $\Phi_{ij} \neq 0$. It is easy to show, by a suitable linear transformation on (q^i, p_i) , that this problem can be mapped to a problem in the noncommutative space, i.e. the one with $\Theta^{ij} \neq 0$, $\Phi_{ij} = 0$. Such a transformation is indeed the essence of the Seiberg-Witten map relating a commutative gauge theory with a B-field to a noncommutative gauge theory without a B-field² [5]. In general, for arbitrary Θ, Φ , one can find linear transformations on (q^i, p_i) in a way transforming their commutation relations to the canonical form; i.e. the one with $\Theta^{ij} = \Phi_{ij} = 0$. In such a situation, we deal essentially with an ordinary QM problem. There is, however, a critical value of the B-field, $\Phi = -\Theta^{-1}$, for which the canonizing linear transformation on (q^i, p_i) becomes singular. In that case the phase space of the particle becomes degenerate and is actually described by half of the coordinates (q^i, p_i) (say by q^i only) and the density of states on the phase space becomes infinity [33]. This means that in the critical case, the momenta of a particle are no longer independent of its coordinates but related to them in a particular way [6, 33]. This is the same situation occurring for a particle in a large magnetic field or in its first Landau level [31, 32], which is usually treated using the Dirac quantization procedure for the constrained systems [31].

In the critical case $\Phi = -\Theta^{-1}$, both q^i and p_i are noncommuting and we can not get rid of the noncommutativity by a linear transformation on (q^i, p_i) . In the context of the noncommutative gauge theory, this is equivalent to the fact that, for the critical value of the noncommutative field strength, $\hat{F} = \Theta^{-1}$, one can not find a commutative description of the same theory [5]. This is the same choice which is naturally singled out by the matrix theory [6]. As explained in [6], in this case the derivative operators ∂_i on functions of the noncommutative space are expressed as commutators with the coordinates and hence they obey the noncommutativity relation $[\partial_i, \partial_j] = -i\Phi_{ij} = i\Theta_{ij}^{-1}$. This means that successive translations in a noncommutative space generally do not commute. When extended to a noncommutative superspace, this raises the question that how the SUSY algebra is affected by turning on the spacetime noncommutativity. It is the purpose of this paper to answer to this question.

²As discussed in [6], the parameters Φ_{ij} in eqs.(1) are the same that appear in the formulation of a NC-DBI action as a freedom to interpolate between several equivalent descriptions of the same theory [5].

In this paper we are mainly interested in the critical ($\Phi = -\Theta^{-1}$) regime in two (Euclidean) dimensions, although most of the results seem to have natural generalizations to the non-critical case and in higher dimensions. More specifically, we are interested in the noncommutative deformation of the $\mathcal{N} = 1$ superalgebra corresponding to a deformation of the two dimensional Euclidean group (briefly denoted as E_{ϑ}^2). The cases of higher dimensional spaces and of the extended SUSY will be investigated elsewhere [40].

The paper is organized as follows. In section 2 we will briefly review the basic notions of superspace and supersymmetry in the commutative theories and then introduce the spacetime noncommutativity and the operator formalism. Then in section 3 we derive the deformed super E^2 algebra corresponding to a noncommutative Euclidean 2D space. The problem of representation and spectrum of the deformed superalgebra is addressed in section 4 and we conclude the paper by a summary and discussion in section 5.

2 Preliminaries and Notations

In this section we first briefly review some elements of SUSY in commutative spaces and then introduce the spacetime noncommutativity and its associated operator formalism. This will fix our notation for the rest of this paper.

2.1 Superspace, Superfields and Ordinary Supersymmetry

Superspace is a mathematical tool invented for simplifying formulation of the SUSY field theories and provides a framework to treat an internal symmetry of a theory in parallel to its spacetime symmetries. The ordinary superspace is defined by the algebra generated by the bosonic and fermionic coordinates (x^a, θ^α) satisfying the following (anti)commutation relations

$$[x^a, x^b] = 0, \quad \{\theta^\alpha, \theta^\beta\} = 0, \quad [x^a, \theta^\alpha] = 0. \quad (2)$$

A general superfield is then an arbitrary function of (x^a, θ^α) . For $\mathcal{N} = 1$, $D = 2$ superspace, we have 2 bosonic and 2 fermionic coordinates and so the indices range as $a = 1, 2$ and $\alpha = +, -$. (see also Appendix for conventions on spinors). A general superfield on this superspace has the following expansion

$$\mathcal{S}(x, \theta) = \phi(x) + \bar{\theta}\psi(x) + \frac{1}{2}\bar{\theta}\theta F(x)$$

$$= \phi(x) + \theta^+ \psi_+(x) + \theta^- \psi_-(x) + \theta^+ \theta^- F(x). \quad (3)$$

For a scalar superfield, $\phi(x), F(x)$ are bosonic scalar fields while $\psi_{\pm}(x)$ form components of a fermionic spinor field. Obviously, the set of all superfields is closed under the ordinary product of superfields with the above (anti)commutation rules.

For later purposes, it is useful to remind the dimensionalities of $\mathcal{S}$, θ , x , which in terms of the length units are written as

$$[\mathcal{S}] = 0, \quad [\theta] = \frac{1}{2}, \quad [x] = 1. \quad (4)$$

The ordinary SUSY can be easily formulated using the concept of “translations” in a superspace. There are two types of these translations which are uniquely determined using dimensional analysis as follows:

1. *Ordinary translation:*

This is a constant shift of x with the vector parameter a

$$\delta_a x^a = a^a, \quad \delta_a \theta^\alpha = 0. \quad (5)$$

2. *Supertranslation:*

This is a constant shift of θ with the spinor parameter ϵ

$$\delta_\epsilon \theta^\alpha = \epsilon^\alpha, \quad \delta_\epsilon x^a = \bar{\epsilon} \rho^a \theta. \quad (6)$$

The appropriate superspace representations of the generators P_a, Q_α of these transformations are simply determined by examining their effects on a general superfield as follows

$$\begin{aligned} \delta_a \mathcal{S} &= a^a \frac{\partial \mathcal{S}}{\partial x^a} \equiv i(a^a P_a) \mathcal{S}, \\ \delta_\epsilon \mathcal{S} &= \epsilon^\alpha \frac{\partial \mathcal{S}}{\partial \theta^\alpha} + \bar{\epsilon} \rho^a \theta \frac{\partial \mathcal{S}}{\partial x^a} \equiv (\bar{\epsilon} Q) \mathcal{S}. \end{aligned} \quad (7)$$

These imply that

$$\begin{aligned} P_a &= -i \frac{\partial}{\partial x^a}, \\ Q_\alpha &= \frac{\partial}{\partial \theta^\alpha} + i(\rho^1 \rho^a)_{\alpha\beta} \theta^\beta \frac{\partial}{\partial x^a}. \end{aligned} \quad (8)$$

Now, using the following properties of the commutative superspace

$$\left[\frac{\partial}{\partial x^a}, \frac{\partial}{\partial x^b} \right] = 0, \quad \left[\frac{\partial}{\partial x^a}, \frac{\partial}{\partial \theta^\alpha} \right] = 0, \quad \left\{ \frac{\partial}{\partial \theta^\alpha}, \frac{\partial}{\partial \theta^\beta} \right\} = 0, \quad (9)$$

together with the above expressions of P, Q , we obtain the ordinary super-translation algebra as follows:

$$\begin{aligned} [P_a, P_b] &= 0, \quad [P_a, Q_\alpha] = 0, \\ \{Q_\alpha, Q_\beta\} &= -2(\rho^1 \rho^a)_{\alpha\beta} P_a. \end{aligned} \quad (10)$$

This indeed defines a subalgebra of the complete super E^2 algebra. The latter is obtained by including in the above algebra the commutators of the $SO(2)$ generator with these (super)translation generators.

The important property of a SUSY transformation is that it changes any superfield to a similar superfield. This means that we can re-arrange $\delta_\epsilon \mathcal{S}$ of eq.(7) in powers of $\theta^\pm$ to obtain

$$\delta_\epsilon \mathcal{S} = \delta_\epsilon \phi(x) + \theta^+ \delta_\epsilon \psi_+(x) + \theta^- \delta_\epsilon \psi_-(x) + \theta^+ \theta^- \delta_\epsilon F(x), \quad (11)$$

from which it follows

$$\begin{aligned} \delta_\epsilon \phi(x) &= \bar{\epsilon} \psi(x), \\ \delta_\epsilon \psi(x) &= (-\rho^a \partial_a \phi(x) + F(x)) \epsilon, \\ \delta_\epsilon F(x) &= -i \bar{\epsilon} \rho^a \partial_a \psi(x). \end{aligned} \quad (12)$$

These are the familiar SUSY transformations of the component fields equivalent to the second eq.(7).

2.2 Noncommutativity of Spacetime

Origin:

Noncommutative field theories (and in particular NCYM theory) arise in the so called decoupling limit of the theory of open strings ending on a D-brane in the presence of a background B-field [5]. String theory calculation of the open string tree amplitudes shows that the low energy dynamics of D-branes in the presence of such a background is modified in a way that all the ordinary products of fields in the usual theory are replaced by the following Moyal (or $\ast$ -) product [5]

$$f(x) \ast g(x) = \exp\left(\frac{i}{2} \Theta^{\mu\nu} \partial_\mu \partial'_\nu\right) f(x) g(x') \big|_{x=x'}. \quad (13)$$

Here, $\Theta^{\mu\nu} = -\Theta^{\nu\mu}$ is the constant noncommutativity tensor which is determined by the closed string background fields. The $\ast$ -product is clearly

a noncommutative operation; i.e. $f * g \neq g * f$ for general f, g . In particular, noncommutativity of the spacetime coordinates is measured by $\Theta^{\mu\nu}$ according to

$$[x^\mu, x^\nu]_* = i\Theta^{\mu\nu}. \quad (14)$$

It can be shown that, for a *constant* $\Theta^{\mu\nu}$, the Moyal product is associative which means that for every triplet of functions $f(x)$, $g(x)$, $h(x)$ we have

$$(f * g) * h = f * (g * h). \quad (15)$$

It turns out that the constancy of Θ (corresponding to a flat closed string background) is essential in proving the associativity of the $*$ -product. Otherwise, it is modified to a so-called Kontsevich product which in general defines a non-associative algebra [39]. Note also that the above associativity property is crucial to the Moyal-Weyl correspondence and hence to the operator formalism which we use as a basic tool during this paper (see below).

The Moyal-Weyl Correspondence:

The noncommutativity and associativity of the $*$ -product suggest that there must be an isomorphism between the algebra of functions on a noncommutative space and that of the operators on some Hilbert space [30]. To see this isomorphism explicitly, let us associate to the coordinates x^μ the operators $\hat{x}^\mu$ satisfying the algebra

$$[\hat{x}^\mu, \hat{x}^\nu] = i\Theta^{\mu\nu}. \quad (16)$$

Any function $f(x)$ is then associated to an operator $\hat{O}_f = \hat{f}(\hat{x})$ (and vice versa) through a one-to-one map defined as

$$f(x) = \int d^n k \, e^{ik \cdot x} \tilde{f}(k) \longleftrightarrow \hat{f}(\hat{x}) = \int d^n k \, e^{ik \cdot \hat{x}} \tilde{f}(k), \quad (17)$$

where $\tilde{f}(k)$ denotes the Furrier transform of $f(x)$. This is called the Moyal-Weyl correspondence. It is easy then to show [30] the following properties

$$\begin{aligned} O_{f*g} &= O_f \cdot O_g, \\ \int d^n x \, f(x) &= (2\pi)^{n/2} \sqrt{\det \Theta} \text{Tr} O_f. \end{aligned} \quad (18)$$

These are the basis of the operator formulation of NCFT's which has played a central role in the development of solitons of these theories [30]. For our purpose, the Moyal-Weyl correspondence is used as a basis for treating functions of a noncommutative space, on equal footing with the symmetry generators, as the operators of some Hilbert space.

3 Noncommutative Supersymmetry

Motivation:

The issue of supersymmetry in NCFT has been considered previously by several authors[16]-[28]. In particular, many perturbative aspects of the noncommutative super Yang-Mills (NCSYM) theory have been studied in many papers (for an exhaustive list of references see [7]). In most of these papers, however, the issue of supersymmetry in NCFT is treated in parallel to what usually is done in their commutative counterpart theories. In other words, one starts with a usual commutative theory based on an ordinary SUSY algebra and then proceed to deform it by replacing the ordinary products of fields with Moyal products. In this way we obtain a noncommutative supersymmetric field theory whose field content obeys the ordinary SUSY transformation properties.

From a more fundamental point of view, however, we know that the SUSY algebra underlying a theory is obtained by extending its usual space-time symmetries including the translations and rotations (or boosts) by inclusion of the supertranslation symmetry. Therefore, one should expect a deformation of SUSY, if the theory allows for a deformation of either of the usual spacetime symmetries. In the case of a NCFT, we know that generally noncommutativity breaks rotational symmetries of the theory but preserves its translational symmetries. On the other hand, we know that there is a freedom in the formulation of a NCFT due to the freedom in the choice of the commutator of any two spatial derivatives; $[\partial_a, \partial_b] = -i\Phi_{ab}$ [6]. Interpreting these derivatives as the generators of translations in the noncommutative directions, we find that the translation algebra is deformed by a central extension. Hence we should expect also a deformation of the corresponding supertranslation algebra.

3.1 Deformed Translation Algebra

Let us consider a noncommutative 2D space with coordinates $\hat{x}^a$ satisfying³

$$[\hat{x}^a, \hat{x}^b] = i\vartheta\epsilon^{ab}. \quad (19)$$

In the operator formulation, derivatives of a field $\hat{\phi}(\hat{x})$ can be expressed as [6, 33]

$$\partial_a \hat{\phi}(\hat{x}) = i\vartheta^{-1}\epsilon_{ab}[\hat{x}^b, \hat{\phi}(\hat{x})]. \quad (20)$$

³In due course we will omit the hat signs on the operators whenever there is no possibility of confusion.

This suggests identifying the momenta $\hat{P}_a$ as the generators of translations in terms of coordinates as follows (see also [34] for this point)

$$\hat{P}_a = \vartheta^{-1} \epsilon_{ab} \hat{x}^b. \quad (21)$$

By the eq.(19), this relation automatically satisfies the Heisenberg equation

$$[\hat{x}^a, \hat{P}_b] = i\delta_b^a. \quad (22)$$

Also from the same constraint it follows that

$$[\hat{P}_a, \hat{P}_b] = i\vartheta^{-1} \epsilon_{ab}, \quad (23)$$

which shows the noncommutativity of momenta in the noncommuting directions. The three eqs.(19), (22), (23) define a deformation of the ordinary Heisenberg algebra on a noncommutative plane in a way consistent with all the Jacobi Identities.

We can reverse this logic in order to conclude eq.(21) in another way. We may start by not assuming any relation between $(\hat{x}, \hat{P})$'s but instead assume a commutation relation between $\hat{P}$'s as follows

$$[\hat{P}_a, \hat{P}_b] = i\omega \epsilon_{ab}. \quad (24)$$

where ω is some real constant. This corresponds to a more general deformation of the Heisenberg algebra involving two arbitrary parameters (ϑ, ω) . The special point $\omega = 1/\vartheta$ corresponds to the previous deformation. For generic values of (ϑ, ω) , the representation space of the deformed Heisenberg algebra is spanned by a 2-parameter set of states with parameters defined by the eigenvalues of the operators in a Cartan subalgebra of $(\hat{x}, \hat{P})$'s. This can be chosen to be $(\hat{x}^1, \hat{P}_2)$ and hence the Hilbert space is spanned by the simultaneous eigenstates $|x^1, p_2\rangle$ of these two operators. In this basis, $(\hat{x}^1, \hat{P}_2)$ have the following simple representations

$$\hat{x}^1 = x^1, \quad \hat{P}_2 = p_2. \quad (25)$$

Comparison to the case of an ordinary Heisenberg algebra then suggests that the other two operators $(\hat{x}^2, \hat{P}_1)$ should have linear representations in terms of $\frac{\partial}{\partial x^1}, \frac{\partial}{\partial p_2}$. The coefficients of these linear representations are fixed by putting them into the algebra and demanding that it holds identically. Thus we find

$$\begin{aligned} \hat{x}^2 &= i \left(-\vartheta \frac{\partial}{\partial x^1} + \frac{\partial}{\partial p_2} \right), \\ \hat{P}_1 &= i \left(-\frac{\partial}{\partial x^1} + \omega \frac{\partial}{\partial p_2} \right). \end{aligned} \quad (26)$$

Clearly, for generic values of ϑ and ω , with $\vartheta\omega \neq 1$, $(\hat{x}^2, \hat{P}_1)$ behave as independent operators. Just at the critical point $\omega = 1/\vartheta$ the two operators become proportional,

$$\hat{P}_1 = \omega \hat{x}^2. \quad (27)$$

The same logic applies if we exchange the role of $(\hat{x}^1, \hat{P}_2)$ with $(\hat{x}^2, \hat{P}_1)$ and the result is

$$\hat{P}_2 = -\omega \hat{x}^1. \quad (28)$$

Hence we see that, for the critical value $\omega = 1/\vartheta$, the operators $\hat{x}^a, \hat{P}_b$ satisfying the deformed Heisenberg algebra must be constrained according to eq.(21). In this case the Hilbert space (representation) of the algebra is no longer defined by the 2-parametric set of states $|x^1, p_2\rangle$ and degenerates to a 1-parametric set of states like $|x^1\rangle$.

It may be amusing to compare the above phenomenon in reduction of the dimension of representation to what happens in the case of a short representation (or BPS states) of an ordinary SUSY algebra. In both cases we deal with an algebra depending on a set of parameters so that on a special boundary in the space of these parameters the dimension of a generic representation suddenly decreases. In the case of a short representation, the parameter space is defined by the mass and charge (m, q) parameters and the boundary is given by the BPS condition, $m = |q|$, on which the dimension of a generic representation is reduced by $\frac{1}{2}$. In our case, the parameter space consists of (ϑ, ω) in which on the critical curve, $\omega = 1/\vartheta$, the basis of the Hilbert space shrinks from a 2-parametric set of states to a 1-parametric set.

3.2 The Noncommutative Superspace and the Deformed Supertranslation Algebra

Our definition of a noncommutative superspace in this paper is a simple extension of the usual noncommutative space endowed with a set of anti-commuting grassmann coordinates. In other words, we define a noncommutative superspace as the algebra of the bosonic and fermionic operators (coordinates) x^a, θ^α satisfying

$$[x^a, x^b] = i\vartheta\epsilon^{ab}, \quad \{\theta^\alpha, \theta^\beta\} = 0, \quad [x^a, \theta^\alpha] = 0. \quad (29)$$

This corresponds to the algebra of derivatives as follows

$$\left[\frac{\partial}{\partial x^a}, \frac{\partial}{\partial x^b}\right] = -i\omega\epsilon_{ab}, \quad \left[\frac{\partial}{\partial x^a}, \frac{\partial}{\partial \theta^\alpha}\right] = 0, \quad \left\{\frac{\partial}{\partial \theta^\alpha}, \frac{\partial}{\partial \theta^\beta}\right\} = 0. \quad (30)$$

We will take $\omega = 1/\vartheta$ in all the subsequent formulae. More generally, we could consider nontrivial (anti)commutation relations also between (θ, θ) and (x, θ) . However, the associativity of the $*$ -product, which amounts to the satisfaction of the Jacobi identities, requires trivial relations of these two types, at least when the noncommutativity parameter (ϑ) is taken a constant [12].

Let us now assume the same definitions as eqs.(5),(6) for the translations and supertranslations on a noncommutative superspace. Therefore, the representations of the corresponding generators are given by the same expressions as in the commutative case (eqs.(8)), except that in this case the derivative operators $\partial/\partial x^a$ do not commute as in eq.(30). Hence, computing the (anti)commutators of those expressions, taking into account the above fact, we obtain the following modified supertranslation algebra

$$\begin{aligned} [P_a, P_b] &= i\omega\epsilon_{ab}, \\ [Q_\alpha, P_a] &= i\omega\epsilon_{ab}(\rho^1\rho^b)_{\alpha\beta}\theta^\beta, \\ \{Q_\alpha, Q_\beta\} &= -2(\rho^1\rho^a)_{\alpha\beta}P_a + i\omega\epsilon_{ab}(\rho^1\rho^a\theta)_\alpha(\rho^1\rho^b\theta)_\beta. \end{aligned} \quad (31)$$

As is seen, all the modification terms are proportional to ω and are written in either of the forms $1, \theta^+, \theta^-, \theta^+\theta^-$, which together form a complete basis on the space of functions of (θ^+, θ^-) . At the first sight, this is not a closed algebra in the sense of ordinary super Lie algebras. However, we find that we can close this algebra by appending to it new operators represented by the above combinations. It turns out [41] that these new operators have the interpretation of the generators of a new “gauge symmetry” of the theory, which are represented on a scalar superfield $S(x, \theta)$ as follows

$$S \rightarrow f(\theta)S, \quad (32)$$

with f being any function of the grassmann odd coordinates. This symmetry gets mixed with the (super)translation symmetries when the space becomes noncommutative. Surprisingly, the above algebra does not reduce to the usual algebra (eq.(10)) in the limit of zero noncommutativity $\vartheta \rightarrow 0$, but it does that in the limit of an infinite noncommutativity $\omega = 1/\vartheta \rightarrow 0$.

3.3 Rotation on a Noncommutative Superspace

So far we have considered only the (super)translation part of the deformed super E^2 algebra. In higher dimensions, the rotational (or Lorentz) symmetries are generally broken by the spacetime noncommutativity so that their

algebra is not consistently closed with the above deformed translation algebra⁴. However, in 2 dimensions the $SO(2)$ symmetry is not broken by the presence of noncommutativity and hence it can be consistently appended to the deformed translation algebra. This is indeed because the basic equation $[x^a, x^b] = i\vartheta\epsilon^{ab}$ is invariant under the usual $SO(2)$ rotations,

$$\delta_\alpha x^a = -\alpha\epsilon^{ab}x^b. \quad (33)$$

Denoting the generator of these rotations by J , we can write the above equation in the operator language as

$$[J, x^a] = -i\epsilon^{ab}x^b. \quad (34)$$

Now, using this equation, the commutator of J with both sides of the eq.(19) becomes

$$\begin{aligned} [J, [x^a, x^b]] &= -[x^b, [J, x^a]] + [x^a, [J, x^b]] \\ &= i\epsilon^{ac}[x^b, x^c] - i\epsilon^{bc}[x^a, x^c] = 0, \end{aligned} \quad (35)$$

showing that the $SO(2)$ rotations are compatible with the algebra defined by eq. (19). A similar fact can be proved for the whole algebra defined by the eqs.(29), taking into account that coordinates θ^α obey the following $SO(2)$ transformations (see also Appendix):

$$\delta_\alpha \theta = i\frac{\alpha}{2}\sigma_3\theta. \quad (36)$$

Let us now consider the $SO(2)$ variation of an arbitrary function $f(x)$ of the noncommutative coordinates. More precisely, we are interested in the $SO(2)$ variation of the operator $\hat{f}(\hat{x})$ which is the Moyal-Weyl correspondent of the ordinary function $f(x)$. This variation must be computed using the expansion of $\hat{f}(\hat{x} + \delta\hat{x})$, taking into account that $\delta\hat{x}$'s do not commute with $\hat{x}$'s, thus preventing the use of the ordinary Taylor series expansion. Given particular polynomial definitions for $\hat{f}(\hat{x})$, it is easy to find $\delta\hat{f}$ by directly calculating $\hat{f}(\hat{x} + \delta\hat{x}) - \hat{f}(\hat{x})$, and ordering the result in powers of $\delta\hat{x}$ using the known expressions for $[\hat{x}^a, \delta\hat{x}^b]$. For a general $\hat{f}(\hat{x})$, however, it is easier to do the same task by going first to the function language and then convert the result into the operator language. For this purpose, we first note that

⁴That is the Jacobi identities are not satisfied for the full Poincare algebra.

$$\delta_\alpha x^a * \partial_a f(x) = \delta_\alpha x^a \partial_a f(x) + \frac{i}{2} \alpha \vartheta \square f(x), \quad (37)$$

where $\square \equiv \partial_a \partial_a$. Hence, using the ordinary Taylor expansion of $f(x + \delta x)$ we find

$$\delta_\alpha f(x) = \delta_\alpha x^a \partial_a f(x) = \delta_\alpha x^a * \partial_a f(x) - \frac{i}{2} \alpha \vartheta \square f(x). \quad (38)$$

By the Moyal-Weyl map on this equation, we then easily find the desired expression

$$\delta_\alpha \hat{f}(\hat{x}) = -\alpha \left(\epsilon_{ab} \hat{x}^b \partial_a \hat{f}(\hat{x}) + \frac{i}{2} \vartheta \square \hat{f}(\hat{x}) \right). \quad (39)$$

Here, the derivative operators are defined through their *adjoint* operations, i.e.,

$$\begin{aligned} \partial_a \hat{f}(\hat{x}) &= i\vartheta^{-1} \epsilon_{ab} [\hat{x}^b, \hat{f}(\hat{x})] \equiv [\hat{\partial}_a, \hat{f}(\hat{x})], \\ \square \hat{f}(\hat{x}) &\equiv [\hat{\partial}_a, [\hat{\partial}_a, \hat{f}(\hat{x})]]. \end{aligned} \quad (40)$$

It is easy to extend the above result to the case of superfields on a noncommutative superspace. The only change is due to the variation of θ^α giving rise to an additional term in the above expression as follows

$$\delta_\alpha \hat{\mathcal{S}}(\hat{x}, \theta) = \alpha \left(-\epsilon_{ab} \hat{x}^b \partial_a - \frac{i}{2} \vartheta \square + \frac{i}{2} \sigma_{\alpha\beta}^3 \theta^\beta \frac{\partial}{\partial \theta^\alpha} \right) \hat{\mathcal{S}}(\hat{x}, \theta). \quad (41)$$

The superspace representation of the $SO(2)$ generator J is read from this expression to be

$$-J = L + S, \quad (42)$$

where

$$\begin{aligned} L &\equiv -i\epsilon_{ab} x^a \partial_b - \frac{1}{2} \omega^{-1} \square, \\ S &\equiv \frac{1}{2} \sigma_{\alpha\beta}^3 \theta^\alpha \frac{\partial}{\partial \theta^\beta}. \end{aligned} \quad (43)$$

This L, S specify the *orbital* and *spin* angular momentum operators, respectively. Compared to the commutative expressions, noncommutativity modifies only the orbital part of J but not its spin part as a result of non-deforming the algebra of the odd coordinates. Now, using the relation (21)

between x, P , or alternatively $\partial_a = i\omega\epsilon_{ab}x^b$, we find that L is written in either of the following forms:

$$L = \frac{1}{2}(x^1 P_2 - x^2 P_1) = -\frac{1}{2\omega}(P_1^2 + P_2^2). \quad (44)$$

The first expression is just 1/2 the classical (commutative) expression of L . It turns out that this factor is crucial in recovering the correct commutation relation between L, P_a , i.e.

$$[L, P_a] = -i\epsilon_{ab}P_b, \quad (45)$$

as is required by the $SO(2)$ transformation of P_a as a vector. The second expression in (44) shows that the orbital the angular momentum of a particle on a noncommutative plane is proportional to its (Euclidean) mass squared $M^2 \equiv (P_1)^2 + (P_2)^2$; i.e.

$$L = -\frac{1}{2\omega}M^2. \quad (46)$$

This is comparable to the expression in [37] for the generator of rotations on the phase space of a particle in 2D. (see also [31])

3.4 The Complete Super E_θ^2 Algebra

We are now ready to obtain the full super E_θ^2 algebra by computing the (anti)commutators of all pairs of its generators P_a, Q_α, J from their explicit representations by eqs.(8), (42), (43). Besides that, we introduce the new operators O_+, O_-, T via their representations (as noted below eq.(31)) as follows

$$O_+ \equiv \theta^-, \quad O_- \equiv \theta^+, \quad T \equiv \theta^+ \theta^-. \quad (47)$$

Further we define the complex momenta as

$$P_\pm \equiv P_1 \mp iP_2 \quad (48)$$

It is now easy to show that the algebra of the generators $P_\pm, Q_\pm, J, O_\pm, T$ is a closed algebra whose non-trivial relations are summarized in the following

$$\begin{aligned} [P_+, P_-] &= 2\omega, & \{Q_+, Q_-\} &= 2\omega T, \\ [Q_+, P_-] &= -2\omega O_-, & [Q_-, P_+] &= 2\omega O_+, \\ (Q_+)^2 &= -P_+, & (Q_-)^2 &= -P_-, \\ \{Q_+, O_-\} &= 1, & \{Q_-, O_+\} &= 1, \end{aligned}$$

$$\begin{aligned}
[Q_+, T] &= O_+, & [Q_-, T] &= -O_-, \\
[J, P_+] &= P_+, & [J, P_-] &= -P_-, \\
[J, Q_+] &= \frac{1}{2}Q_+, & [J, Q_-] &= -\frac{1}{2}Q_-, \\
[J, O_+] &= \frac{1}{2}O_+, & [J, O_-] &= -\frac{1}{2}O_-.
\end{aligned} \tag{49}$$

This is a consistent super Lie algebra in the sense that the coefficients on its RHS have been set in a way that it automatically satisfies the Jacobi identities. For example, using this algebra, one can easily verify the following identities

$$\begin{aligned}
[Q_+, \{Q_+, Q_-\}] + [Q_+, \{Q_-, Q_+\}] + [Q_-, \{Q_+, Q_+\}] &= \\
2\omega O_+ + 2\omega O_+ - 4\omega O_+ &= 0, \\
[P_+, \{Q_-, Q_-\}] + \{Q_-, [Q_-, P_+]\} + \{Q_-, [Q_-, P_+]\} &= \\
-4\omega + 2\omega + 2\omega &= 0, \\
[J, \{Q_+, Q_+\}] + \{Q_+, [Q_+, J]\} + \{Q_+, [Q_+, J]\} &= \\
-2P_+ + P_+ + P_+ &= 0, \\
[J, \{Q_+, Q_-\}] + \{Q_+, [Q_-, J]\} + \{Q_-, [Q_+, J]\} &= \\
0 + \omega T - \omega T &= 0, \\
[J, [Q_+, T]] + [Q_+, [T, J]] + [J, [Q_+, T]] &= \\
O_+ + 0 - O_+ &= 0.
\end{aligned} \tag{50}$$

This is not a surprising feature of the algebra as it was derived using explicit representations for its generators on a Hilbert space consisting of all the superfields on the given (noncommutative) superspace. Such an algebra must necessarily satisfy the Jacobi identities as a result of its *associativity*.

As is clear, the modifications due to the noncommutativity of space appear *only* in the P, Q sector of the above algebra. More significantly, all the noncommutativity modifications, which are proportional to $1, O_\pm, T$, commute with any (operator valued) superfield $\hat{S}(\hat{x}, \theta)$, since they do not depend on $\hat{x}^a$ at all. Due to this feature, these modifications are not observable in the algebra of the SUSY variations in a NCFT which is a Moyal deformation of a usual SUSY field theory (see next section).

Finally, we note that the operators $Q_\pm$ ($P_\pm$) behave as the ladder operators of J shifting its eigenvalue by $\pm 1/2$ (± 1) units.

4 Spectrum of the Super $E_{\mathfrak{g}}^2$ Algebra

4.1 The Purely Bosonic Case

Let us begin the analysis of the spectrum by considering first the spectrum of the purely bosonic translation subalgebra,

$$[P_+, P_-] = 2\omega. \quad (51)$$

Noting to $(P_+)^\dagger = P_-$, this is reduced to a simple harmonic oscillator algebra by taking

$$\begin{aligned} P_+ &= \sqrt{2\omega}a, & P_- &= \sqrt{2\omega}a^\dagger, \\ [a, a^\dagger] &= 1. \end{aligned} \quad (52)$$

The Euclidean mass squared operator in two dimensions,

$$M^2 = P_1^2 + P_2^2 = P_+P_- - \omega = P_-P_+ + \omega, \quad (53)$$

is proportional to the Hamiltonian of the harmonic oscillator, i.e.

$$M^2 = 2\omega \left(a^\dagger a + \frac{1}{2} \right). \quad (54)$$

So, the representation space of the translation algebra in two dimensions is spanned by the energy eigenstates of a harmonic oscillator in one dimensions, which are the same as the mass eigenstates in two dimensions; i.e.

$$\mathcal{H} = \text{span}\{|n\rangle; \quad (a^\dagger a)|n\rangle = n|n\rangle; \quad n = 0, 1, 2, \dots\}. \quad (55)$$

The corresponding M^2 eigenvalues are

$$m_n^2 = 2\omega \left(n + \frac{1}{2} \right), \quad (56)$$

which by eq.(46) correspond to the quantized values of L as follows

$$l_n = - \left(n + \frac{1}{2} \right). \quad (57)$$

The effect of $P_\pm$ on this spectrum of states is simply to higher or lower the value of n according to

$$a|n\rangle = \sqrt{n}|n-1\rangle, \quad a^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle. \quad (58)$$

This is indeed a basis for the *fundamental* representation of the noncommutative translation algebra. Alternatively, we can construct an *adjoint*

representation by forming a basis on the space of the operators in terms of the states $|n\rangle$

$$\mathcal{H}^* = \text{span}\{|m\rangle\langle n|; \quad m, n = 0, 1, 2, \dots\}. \quad (59)$$

A *unitary* transformation $U = e^{iA}$ corresponding to a symmetry operation in the completed algebra acts on $\mathcal{H}$ and $\mathcal{H}^*$ as follows

$$\begin{aligned} |n\rangle &\longrightarrow U|n\rangle, \\ |m\rangle\langle n| &\longrightarrow U|m\rangle\langle n|U^\dagger. \end{aligned} \quad (60)$$

Now, since any field $\widehat{\phi}(\widehat{x})$ in the operator formulation has an expansion in the basis defined in eq.(59),

$$\widehat{\phi}(\widehat{x}) = \sum_{m,n=0}^{\infty} c_{mn} |m\rangle\langle n|, \quad (61)$$

the above unitary transformation must change $\widehat{\phi}(\widehat{x})$ as

$$\widehat{\phi}(\widehat{x}) \rightarrow U\widehat{\phi}(\widehat{x})U^\dagger. \quad (62)$$

For an infinitesimal transformation of this kind, the change of a field in NCFT in either of its operator and ordinary formulations becomes

$$\delta_A \widehat{\phi}(\widehat{x}) = i[\widehat{A}, \widehat{\phi}(\widehat{x})] \quad \leftrightarrow \quad \delta_A \phi(x) = i[A(x), \phi(x)]_*. \quad (63)$$

Here, the operators $\widehat{A}, \widehat{\phi}(\widehat{x})$ and the functions $A(x), \phi(x)$ are related by the Moyal-Weyl map. This shows that the noncommutative fields always transform in the adjoint representation of the noncommutative supergroup. A direct consequence of this fact is that it is not possible to observe the non-commutativity modifications of the superalgebra in a NCFT which is obtained by Moyal deformation of an ordinary SUSY field theory [19]. This is because all the modifications found in eqs.(49), being pure functions of θ^α , commute with any superfield $\widehat{\mathcal{S}}(\widehat{x}, \theta)$. As a result, these modifications are removed from all the commutators, if one tries to recover the superalgebra through the algebra of the variations of the superfields (e.g. $[\delta_A, \delta_B]\widehat{\mathcal{S}}$ for each pair of the generators A, B), and hence, the superalgebra is apparently unchanged. This is compatible with the result of [19] found in the context of the noncommutative WZ model using explicit expressions for its conserved (super)charges.

4.2 The Supersymmetric Case

The commutative limit:

Before completing the spectrum of the super E^2_{θ} algebra, it is worthwhile to have a look at its commutative counterpart which is obtained by going to the $\omega \rightarrow 0$ limit. More precisely, when $\omega = 0$ in eqs.(49), we obtain two separated subalgebras, one for $P_a, Q_\alpha, O_\alpha, T$ and the other for P_a, Q_α, J , which the latter defines the commutative super E^2 algebra through the non-vanishing (anti)commutators:

$$\begin{aligned} Q_+^2 &= -P_+, & Q_-^2 &= -P_-, \\ [J, P_\pm] &= \pm P_\pm, & [J, Q_\pm] &= \pm \frac{1}{2} Q_\pm. \end{aligned} \quad (64)$$

This algebra has a single Casimir operator which is defined by the mass squared:

$$M^2 = P_+ P_- . \quad (65)$$

This is an $SO(2)$ -invariant quantity and hence commutes with J ,

$$[M^2, J] = 0. \quad (66)$$

Indeed, (M^2, J) form the maximal commuting set of operators for the super E^2 algebra and so an *irreducible* representation of this algebra is spanned by the simultaneous eigenstates of these operators:

$$\begin{aligned} M^2 |m, j\rangle &= m^2 |m, j\rangle, \\ J |m, j\rangle &= j |m, j\rangle. \end{aligned} \quad (67)$$

Here, the mass squared eigenvalue m^2 is any *positive* or *negative* real number, provided we do not assume any restriction on the positive-definiteness of the norm in the Hilbert space. On the other hand, the angular momentum eigenvalue j in 2D (despite in higher dimensions) is not restricted to half-integers, but it takes *continuous* real values. However, because of the $\pm 1/2$ shifts of j due to the action of $Q_\pm$, any irreducible representation of the algebra consists only of those states whose values of j differ by the half integers. This means that different irreducible representations of the super E^2 algebra (for a fixed m^2) are distinguished by a real number ν , $0 \leq \nu < \frac{1}{2}$, which restricts the values of j to $j = \nu + \frac{n}{2}$, with $n \in \mathbb{Z}$. We note that, for a fixed m^2 , the states $|m, j\rangle$ for different j 's are orthogonal since J is a Hermitian operator.

The action of $Q_{\pm}$ on these states is specified as follows

$$Q_{\pm}|m, j\rangle = C_{\pm}(m, j)|m, j \pm \frac{1}{2}\rangle, \quad (68)$$

where $C_{\pm}(m, j)$ are coefficients to be determined. The action of $P_{\pm}$ in this representation is then specified by simply acting twice by $Q_{\pm}$ which using the above equation becomes

$$P_{\pm}|m, j\rangle = -C_{\pm}(m, j)C_{\pm}(m, j \pm \frac{1}{2})|m, j \pm 1\rangle. \quad (69)$$

Taking the inner product of eqs.(68),(69) with another arbitrary state of representation, $|m, j'\rangle$, and also using the norms of the same equations, we obtain a set of equations involving the constants $C(m, j)$ and the norms of states $\langle m, j|m, j\rangle$ for different j 's. These can be analyzed in detail and give the following results:

a) For $m^2 > 0$, all the states $|m, j\rangle$ in the representation are *null* and, with a suitable choice of their normalizations, we can write

$$\begin{aligned} C_+(m, j) &= -\sqrt{m}, & C_-(m, j) &= i(-1)^{[2j]}\sqrt{m}, \\ \langle m, j|m, j\rangle &= 0. \end{aligned} \quad (70)$$

Here $[x]$ denotes the integer part of the real number x .

b) For $m^2 = 0$, we have the following restrictions between $C_{\pm}$ and the norm of the states

$$\begin{aligned} C_+(0, j)C_-(0, j + 1/2) &= 0, \\ C(0, j \pm 1/2)\langle 0, j|0, j\rangle &= 0, \end{aligned} \quad (71)$$

which allows for both the positive and negative normed states, as well as the null states.

c) For $m^2 = -\mu^2 < 0$, we have both positive and negative normed states in the representation and, with a suitable normalization, we can write

$$\begin{aligned} C_+(\mu, j) &= -\sqrt{\mu}, & C_-(\mu, j) &= (-1)^{[2j]}\sqrt{\mu}, \\ \langle \mu, j|\mu, j\rangle &= (-1)^{\frac{1}{2}[2j]([2j]-1)}. \end{aligned} \quad (72)$$

We can construct *reducible* representations of the algebra out of the tensor products of two of its irreducible representations. For example, in the superfield representation on a Euclidean $\mathbb{R}^2$ plane, we indeed use the tensor

product of a representation with $j \in \mathbb{Z}$ but with an arbitrary m^2 , and another one with $j = 0, \pm\frac{1}{2}$ and $m^2 = 0$, corresponding to the functions of the form $f(x)$ and $g(\theta)$, respectively. Other geometries may also be handled by using other representations of the same algebra. For example, with $j \notin \mathbb{Z}$ in the first representation, we could obtain a superfield representation on a conic geometry rather than on the Euclidean plane.

The noncommutative case:

With insights from the commutative limit, it must now be evident that finding the spectrum of the complete super E_{θ}^2 algebra is equivalent to finding a suitable basis for the expansion of a noncommutative superfield. Any such superfield is expressed, via a Moyal-Weyl map, as an operator,

$$\widehat{\mathcal{S}}(\widehat{x}, \theta) = \widehat{\phi}(\widehat{x}) + \theta^+ \widehat{\psi}_+(\widehat{x}) + \theta^- \widehat{\psi}_-(\widehat{x}) + \theta^+ \theta^- \widehat{F}(\widehat{x}), \quad (73)$$

whose components $(\widehat{\phi}, \widehat{F}, \widehat{\psi}_{\pm})$ are themselves a set of (bosonic or fermionic) operators. Taking the basis for functions of $\widehat{x}$ as in eq.(59) and that of functions of θ as

$$\mathcal{K} = \text{span}\{1, \theta^+, \theta^-, \theta^+ \theta^-\}, \quad (74)$$

the representation space of our algebra in the adjoint case is simply spanned by the tensor product

$$\mathcal{L}^* = \mathcal{H}^* \otimes \mathcal{K}. \quad (75)$$

The corresponding basis for $\widehat{\mathcal{S}}(\widehat{x}, \theta)$ is thus of the form: $|m, n\rangle|i\rangle$ ($m, n = 0, 1, 2, \dots$ and $i = 1, \dots, 4$), where $|i\rangle \in \mathcal{K}$ is one of the four states represented by $1, \theta^+, \theta^-, \theta^+ \theta^-$. Alternatively, we could construct the fundamental representation by taking the tensor product

$$\mathcal{L} = \mathcal{H} \otimes \mathcal{K}, \quad (76)$$

whose basis vectors consist of the states of the form $|n\rangle|i\rangle$.

It is useful to organize the states in $\mathcal{K}$ according to the eigenvalues of the two commuting operators R, S defined as follows

$$\begin{aligned} R &\equiv \frac{1}{2} \left(\theta^+ \frac{\partial}{\partial \theta^+} + \theta^- \frac{\partial}{\partial \theta^-} \right), \\ S &\equiv \frac{1}{2} \left(\theta^+ \frac{\partial}{\partial \theta^+} - \theta^- \frac{\partial}{\partial \theta^-} \right). \end{aligned} \quad (77)$$

The operator S here is the same as the spin operator defined by eq.(43). Indeed, the eigenvalues of S specify the spins of the states in $\mathcal{K}$ while those

of R specify their length dimensions. It is easy to see that these operators satisfy the following equations

$$\begin{aligned} 2R^3 - 3R^2 + R &= 0, \\ 4S^3 - S &= 0. \end{aligned} \quad (78)$$

showing that R and S have the eigenvalues $r = 0, \frac{1}{2}, 1$ and $s = -\frac{1}{2}, 0, \frac{1}{2}$, respectively. One can then easily check that the basis vectors in $\mathcal{K}$ are the simultaneous eigenstates of R, S , which henceforth are identified with $|r, s\rangle$ as follows

$$\begin{aligned} |\tfrac{1}{2}, \tfrac{1}{2}\rangle &\equiv (2\omega)^{-\frac{1}{4}}\theta^+, & |\tfrac{1}{2}, -\tfrac{1}{2}\rangle &\equiv (2\omega)^{-\frac{1}{4}}\theta^-, \\ |0, 0\rangle &\equiv 1, & |1, 0\rangle &\equiv (2\omega)^{-\frac{1}{2}}\theta^+\theta^-. \end{aligned} \quad (79)$$

and all other combinations of r, s are identified with the zero state. It is then easy to express the operations of $\theta^\alpha, \partial/\partial\theta^\alpha$ on each of the states $|r, s\rangle$ in terms of some other $|r, s\rangle$.

An arbitrary state $|f\rangle$ in $\mathcal{K}$ is expressed as a function $f(\theta)$ of the Grassmann coordinates. A natural definition of the inner product in $\mathcal{K}$ for two states $|f\rangle, |g\rangle$ is given by

$$\langle f|g\rangle = \int d^2\theta f^*(\theta)g(\theta). \quad (80)$$

Using this definition, one can check that the chosen basis for $\mathcal{K}$ is orthogonal. On the other hand, defining the norm in $\mathcal{K}$ as usual by $\|f\|^2 \equiv \langle f|f\rangle$, one finds that $\mathcal{K}$ contains both positive and negative normed states as well as null states.

Now that the effects of $(a, a^\dagger)$ on the states in $\mathcal{H}$ or $\mathcal{H}^*$ and that of $(\theta^\alpha, \partial/\partial\theta^\alpha)$ on the states in $\mathcal{K}$ are well understood, the problem of representation of the super E^2 algebra reduces to expressing all its generators in terms of $(a, a^\dagger, \theta^\alpha, \partial/\partial\theta^\alpha)$. Using the previous representations of these generators, thus we find

$$\begin{aligned} P_+ &= \sqrt{2\omega}a, & P_- &= \sqrt{2\omega}a^\dagger, \\ Q_+ &= \frac{\partial}{\partial\theta^-} - \sqrt{2\omega}\theta^-a, & Q_- &= \frac{\partial}{\partial\theta^+} - \sqrt{2\omega}\theta^+a, \end{aligned} \quad (81)$$

$$O_+ = \theta^-, \quad O_- = \theta^+, \quad T = \theta^+\theta^-, \quad (82)$$

$$J = \left(a^\dagger a + \frac{1}{2}\right) - \frac{1}{2}\left(\theta^+ \frac{\partial}{\partial\theta^+} - \theta^- \frac{\partial}{\partial\theta^-}\right). \quad (83)$$

For the states in the fundamental representation, $|n\rangle|r, s\rangle$, these generators act as operators from the left, while for the states in the adjoint representation, $|m, n\rangle|r, s\rangle$, the generators act via taking their (anti)commutators with these states⁵. As such, we obtain the two representations of the algebra (49) as follows

The Fundamental Representation:

$$\begin{aligned}
P_+|n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{2}}\sqrt{n}|n-1\rangle|r, s\rangle, \\
P_-|n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{2}}\sqrt{n+1}|n+1\rangle|r, s\rangle, \\
Q_+|n\rangle|r, s\rangle &= (-)^{r+s}(2\omega)^{\frac{1}{4}}\left(|n\rangle|r+\frac{1}{2}, s-\frac{1}{2}\rangle - \sqrt{n}|n-1\rangle|r-\frac{1}{2}, s+\frac{1}{2}\rangle\right), \\
Q_-|n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{4}}\left(|n\rangle|r-\frac{1}{2}, s-\frac{1}{2}\rangle - \sqrt{n+1}|n+1\rangle|r+\frac{1}{2}, s+\frac{1}{2}\rangle\right), \\
J|n\rangle|r, s\rangle &= \left(n-s+\frac{1}{2}\right)|n\rangle|r, s\rangle, \\
O_+|n\rangle|r, s\rangle &= (2\omega)^{-\frac{1}{4}}|n\rangle|r+\frac{1}{2}, s+\frac{1}{2}\rangle, \\
O_-|n\rangle|r, s\rangle &= (-)^{r+s}(2\omega)^{-\frac{1}{4}}|n\rangle|r+\frac{1}{2}, s-\frac{1}{2}\rangle, \\
T|n\rangle|r, s\rangle &= (-)^{r+s+1}(2\omega)^{-\frac{1}{2}}|n\rangle|r+1, s\rangle.
\end{aligned} \tag{84}$$

The Adjoint Representation:

$$\begin{aligned}
P_+|m, n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{2}}\left(\sqrt{m}|m-1, n\rangle|r, s\rangle - \sqrt{n+1}|m, n+1\rangle|r, s\rangle\right), \\
P_-|m, n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{2}}\left(\sqrt{m+1}|m+1, n\rangle|r, s\rangle - \sqrt{n}|m, n-1\rangle|r, s\rangle\right), \\
Q_+|m, n\rangle|r, s\rangle &= (-)^{r+s}(2\omega)^{\frac{1}{4}}\left(\begin{array}{c} |m, n\rangle|r-\frac{1}{2}, s+\frac{1}{2}\rangle \\ -\sqrt{m}|m-1, n\rangle|r+\frac{1}{2}, s-\frac{1}{2}\rangle \\ +\sqrt{n+1}|m, n+1\rangle|r+\frac{1}{2}, s-\frac{1}{2}\rangle \end{array}\right), \\
Q_-|m, n\rangle|r, s\rangle &= (2\omega)^{\frac{1}{4}}\left(\begin{array}{c} |m, n\rangle|r-\frac{1}{2}, s-\frac{1}{2}\rangle \\ -\sqrt{m+1}|m+1, n\rangle|r+\frac{1}{2}, s+\frac{1}{2}\rangle \\ +\sqrt{n}|m, n-1\rangle|r+\frac{1}{2}, s+\frac{1}{2}\rangle \end{array}\right), \\
J|m, n\rangle|r, s\rangle &= (m-n-s)|m, n\rangle|r, s\rangle, \\
O_+|m, n\rangle|r, s\rangle &= O_-|m, n\rangle|r, s\rangle = T|m, n\rangle|r, s\rangle = 0.
\end{aligned} \tag{85}$$

⁵Recall that the states in the adjoint representation $\mathcal{L}^*$ are in the form of operators acting on the states in the fundamental representation $\mathcal{L}$.

As we see, despite in the commutative case, here the angular momentum parameter is not arbitrary but restricted to integer and half integer values in both representations. In the fundamental case it equals to

$$j = n - s + \frac{1}{2}, \quad (86)$$

while in the adjoint case it is given by

$$j = m - n - s. \quad (87)$$

In both cases one can find $SO(2)$ invariant states solving the $j = 0$ condition. In particular, in the adjoint representation, we find the $s = 0$, $m = n$ solution corresponding to $|n\rangle\langle n|$ states, which form a complete basis of radially symmetric configurations for a scalar field on a noncommutative plane [30]. The last line in eq.(85) is another indication that the states of the adjoint representation (i.e. the noncommutative fields) do not “feel” the effect of the new transformations generated by $O_{\pm}$, T . This is why the modifications of eqs.(49) do not appear in the algebra of a supersymmetric NCFT.

5 Conclusion

We can summarize the main results of this paper as follows:

- 1) We found a noncommutative generalization (deformation) of the standard super E^2 algebra with $\mathcal{N} = 1$ SUSY. The generalized algebra involves new generators which constitute the basis of the grassmann algebra in 2 dimensions.
- 2) The construction was based on a constraint relating the momenta to the coordinates of a particle on a noncommutative plane. This could be interpreted, as in the noncommutative Landau problem, as working in the regime with the critical value of the magnetic field $\Phi = -\Theta^{-1}$.
- 3) The deformed algebra goes back to its non-deformed (commutative) version in the limit of infinite noncommutativity ($\vartheta \rightarrow \infty$).
- 4) We found the spectrum of the deformed superalgebra both in its fundamental and adjoint representations. The spectrum essentially consists of the tensor product of the mass eigenstates with the spin eigenstates.
- 5) The mass and orbital angular momentum operators were found to be related as $L = -\frac{1}{2}\vartheta M^2$. Both the mass and angular momentum eigenvalues are quantized. Despite in the commutative case, the mass operator is not a

Casimir of the algebra and as a result the (super)translation generators mix several mass eigenstates.

A generic feature of the deformation found in this paper (which can be easily generalized to other superalgebras in higher dimensions) is that, despite in the commutative spaces, several SUSY generators have non-vanishing (anti)commutators with themselves and with the translation generators. Further, these non-vanishing (anti)commutators are not of the same type as the (super)translation generators, but they involve new types of generators. This is in contrast to another type of deformation found in [8] for the case of a constant H -field background, which also have similar non-vanishing (anti)commutators, but of course without any new generators.

We pointed out that the modifications of the superalgebra of the type that were found in this paper are not observable in the NCFT's which are Moyal deformations of the ordinary SUSY field theories. This is due to the fact that the fields in such theories transform in the adjoint representation of the supergroup and they do not carry the “charges” of the new generators in the algebra. Alternatively, the modifications become observable in a field theory whose field content transform in the fundamental representation of the supergroup. In that case the additional generators would be interpreted as the generators of some new symmetries of the underlying theory [41].

6 Appendix: Spinors in 2 Dimensions

In this appendix we present some of the properties of 2D spinors that are necessary for fixing our notations and conventions throughout this paper. We work with a flat spacetime with the Cartesian coordinates x^a , which is endowed with the Euclidean metric δ_{ab} ($a, b = 1, 2$). The isometry group of this space is the Euclidean group E^2 consisting of the $SO(2)$ rotations and 2D translations. Dirac spinors in 2D have $2^{[D/2]} = 2$ complex components and they can be reduced to minimal spinors with 2 real components or, alternatively, 2 complex components conjugate to each other. A real spinorial representation of the $SO(2)$ group is defined as a two component object θ , which under the $SO(2)$ rotations

$$\begin{pmatrix} x^1 \\ x^2 \end{pmatrix} \rightarrow \begin{pmatrix} \cos \alpha & -\sin \alpha \\ \sin \alpha & \cos \alpha \end{pmatrix} \begin{pmatrix} x^1 \\ x^2 \end{pmatrix}, \quad (\text{A.1})$$

it is transformed as follows

$$\begin{pmatrix} \theta^1 \\ \theta^2 \end{pmatrix} \rightarrow \begin{pmatrix} \cos \frac{\alpha}{2} & -\sin \frac{\alpha}{2} \\ \sin \frac{\alpha}{2} & \cos \frac{\alpha}{2} \end{pmatrix} \begin{pmatrix} \theta^1 \\ \theta^2 \end{pmatrix}. \quad (\text{A.2})$$

From a suitable combination of the bilinear products $\theta^\alpha \theta^\beta$ one can form $SO(2)$ scalars and vectors. Defining the complex coordinate $z \equiv x^1 + ix^2$ and the complex spinor θ with its components $\theta^\pm \equiv \theta^1 \pm i\theta^2$ (hence $(\theta^+)^* = \theta^-$), one can rewrite the above $SO(2)$ transformations as follows

$$\begin{aligned} z &\rightarrow e^{i\alpha} z, \\ \theta &\rightarrow e^{i\alpha\sigma^3/2} \theta. \end{aligned} \quad (\text{A.3})$$

We recall that the spinorial degrees of freedom are taken as grassmann anticommuting numbers throughout this paper. It is easy then to form bilinear invariants out of two grassmann spinors θ, ψ in the above complex representation. This gives

$$\begin{aligned} \text{scalar} &: \quad \bar{\theta}\psi, \\ \text{pseudo scalar} &: \quad i\bar{\theta}\sigma^3\psi, \\ \text{vector} &: \quad \bar{\theta}\rho^a\psi. \end{aligned} \quad (\text{A.4})$$

where $\bar{\theta}$ is defined as

$$\bar{\theta} \equiv -\theta^\dagger \sigma^3, \quad (\text{A.5})$$

and ρ^a are Dirac gamma matrices in 2 Euclidean dimensions which satisfy the Clifford algebra of $SO(2)$,

$$\{\rho^a, \rho^b\} = 2\delta^{ab}. \quad (\text{A.6})$$

We use the following representation of these matrices

$$\rho^1 = \sigma^2, \quad \rho^2 = \sigma^1. \quad (\text{A.7})$$

In these formulae, $\sigma^1, \sigma^2, \sigma^3$ denote the standard Pauli matrices. It is obvious that in this representation $(\rho^a)^\dagger = \rho^a$. We can easily show that the following properties hold

$$\begin{aligned} (\bar{\theta}\psi)^* &= \bar{\theta}\psi = -\bar{\psi}\theta, \\ (\bar{\theta}\sigma^3\psi)^* &= -\bar{\theta}\sigma^3\psi = \bar{\psi}\sigma^3\theta, \\ (\bar{\theta}\rho^a\psi)^* &= \bar{\theta}\rho^a\psi = -\bar{\psi}\rho^a\theta. \end{aligned} \quad (\text{A.8})$$

It is useful to define the lower indices for the spinorial components. These are defined as follows

$$\theta_+ = \theta^-, \quad \theta_- = -\theta^+. \quad (\text{A.9})$$

Using this notation, the scalar quantities $\bar{\theta}\psi$, $\bar{\theta}\sigma^3\psi$ in components are written as

$$\begin{aligned} \bar{\theta}\psi &= \theta^+\psi_+ + \theta^-\psi_-, \\ \bar{\theta}\sigma^3\psi &= \theta^+\psi_+ - \theta^-\psi_-. \end{aligned}$$
